

## Computer Network

IIT2018187

Q) a) Explain briefly the responsibilities and list for each layer of ISO - OSI model. How OSI model is diff from TCP/IP

Ans OSI stand for Open System Interconnection.

There are 7 layer of collaborately to transmit the data from one person to another person

Physical layer.

## The function of physical layer

1. Bit synchronization:
2. Bit rate control:
3. Physical topologies:
4. Transmission node:  
Ex: Hub, repeater, modem, cable
5. Data link layer

The data link layer responsible for node to node delivery of the message.

When packet arrives it is responsibilities of DLL to transmit it to the host using MAC add.

DLL divided into two sub layer

6. Logical link layer
7. Media Access Control

### Function

- 1) Framing
- 2) Physical addressing
- 3) Error control
- 4) Flow control
- 5) Access control

Ex: Switch & Bridge are data link layer

### 3) Network Layer

It is for transmission of data from one host to the another.

- Routing: which route is suitable from source to destination.

### 2. Logical Addressing.

In order to identify each device on internetwork uniquely by its own IP addresses.

Ex: Router work on ~~that~~ this layer & segments is referred as packet in that layer.

### 4) Transport Layer

It is responsible for end to end delivery.

- At sender side

segmentation & flow & error control

- At receiver side

1) Segmentation & Reassembly  
2) Service point adaption  
It is known as Heart of OSI

## 2) Session layer

- 1) Maintenance
- 2) Synchronization
- 3) Drafting controller

## 3) Presentation

Translation  
Encryption / Decryption  
Compression

## 4) Network layer

Produce the data which has to be transferred over the network

## Difference betw OSF & TCP

OSF

TCP

- 1) clear distinction b/w interface & protocol. not any clear distinction b/w them.
- 2) routing standard & protocol defined. It uses Internet Layer
- 3) seven layer. Three layers
- 4) min size of header is 5 bytes. min size of layer is 8 bytes

## Layers in TCP/IP

- 1) network layer
- 2) physical transmission
- 3) It is internet layer
- 4) encapsulate by 2 protocol

## Internet layer

- 1) IP
- 2) ICMP
- 3) ARP

3) Host to Host layer

- a) TCP
- b) UDP

4) App layer or

- a) HTTP
- b) SSH
- c) NTP

5)

Q) `int accept(int sockfd, struct sockaddr *addr, socklen_t *addrlen);`

a) sockfd: To created socket bind to local address with bind() & is listening for connection `listen()`

b) addr: It is pointer to a `sockaddr` struct. It is filled with address of the peer socket as known to the communication layer. The exact format of the address returned is determined by socket's address family.

When `addr` is NULL nothing is filled in. In this case `addrlen` is not used.

c) addrlen → It is ~~size~~ length size of actual peer address.

## Returns

On Success these system call return a non-negative integer that is file descriptor for accepted socket, on error it gives -1.

```
int connect(int sockfd  
           struct sockaddr *serv_addr, socklen_t  
           addr len);
```

sock-fd → file descriptor to add  
specified by addr

addr → address

add → define before

it returns non-negative integer which is file descriptor of connecting socket

## Relationship

The request generated by this connect call is processed by the remote server and is an operating system buffer

The waiting to be handed over to application which will be calling the accept function. The accept call is the mechanism by which the networking program on the server receives those requests that have been accepted by OS.

(ii) ~~is~~ Advantage of Differential manch

- i) A transition is guaranteed at least once every bit for robust clock recovery.
- ii) In a noisy environment identifier transition is less error-prone than comparison signal value against a threshold

Disadvantage

It needs more bandwidth than any other encoding

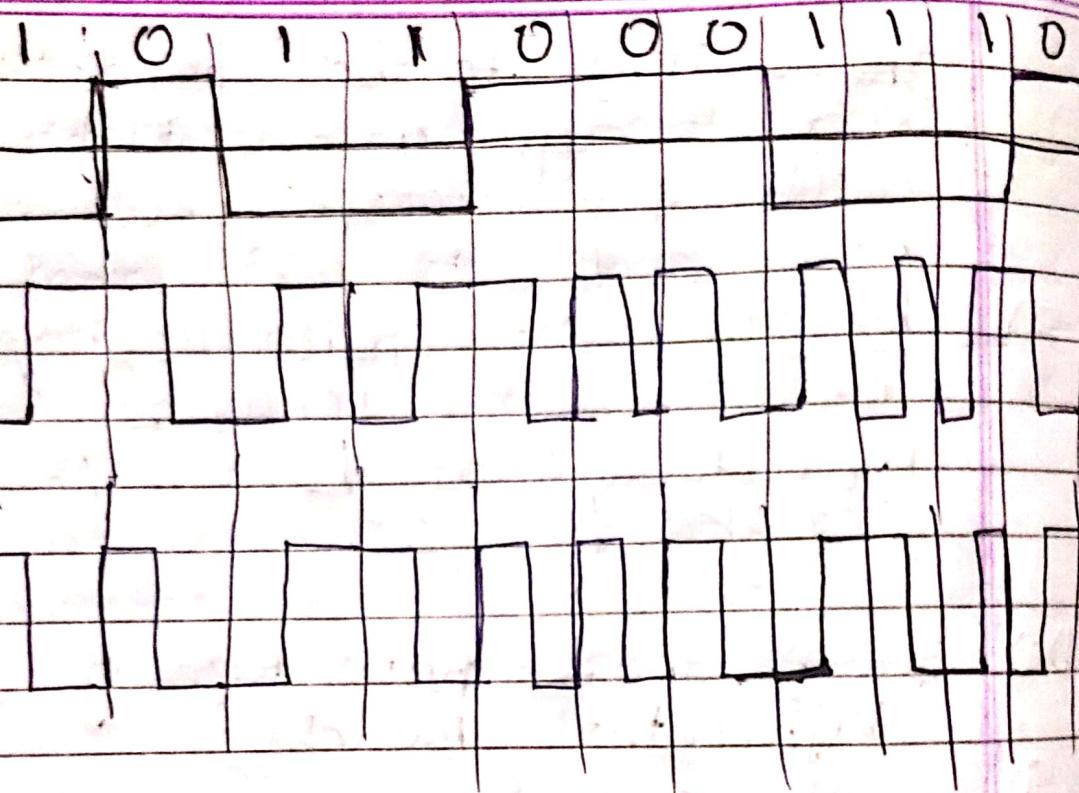

It is self clocking & operate by sensing

2) Three things that IPv6 introduce that should make routing simpler.

i) Built in (QoS) quality of service that distinguish delay sensitive packets

→ Quality of service refer to any technology that manage data traffic

ii) Built in network layer security

Internet based security (IPsec)  
was designed to provide  
network layer security

iii) more simplified header  
structure

When compared to IPv4,  
IPv6 has much simpler  
header structure which is  
essentially designed to minimize  
the time & efforts that go  
into header processing.

2) b) Link State routing Algorithm  
Link state algorithm can transmit  
routing information to all

Page No.	
Date:	

other sending the same protocol, not just objectly

connected neighbours this way all router are receiving first hand information. This makes the router more reliable.

Hence, router create by link state routing protocols generally have lower administrative distance.

They generally use slightly a more ~~advanced~~ advanced algorithm for computing the best route to a destination. One commonly used algo is Dijkstra's shortest path

Difference b/w Link state & Distance vector protocol

## Link State

- Based on adj matrix

- Supports contiguous subnets

- Cost is metric of link state routing protocol

- Supports VLSM  
CIDR

Page No.

Date:

## Distance Vector

- Based on Bellman Ford

- Supports discontinuous subnets

- Distance vector routing uses hop count and composite metric

- Does not support VLSM CIDR

### Q) Question 1 a)

Suppose that a ~~digitized~~ digitalized TV picture is to be no of pixel =  $30 \times 480 \times 500 = 7.2 \times 10^6$  PLS

$$\begin{aligned} C &= 5 \times 7.2 \times 10^6 \\ &= 36 \times 10^6 \text{ bits/s} \\ &= 36 \text{ Mbps} \end{aligned}$$

$$C = B \log_2 \left( 1 + \frac{S}{N} \right)$$

$$B = \frac{C}{\log_2 (1 + S/N)}$$

$$B = \frac{36 \times 10^6}{\log_2 (1 + 3162.27)}$$

$$= \frac{36 \times 10^6}{11.62}$$

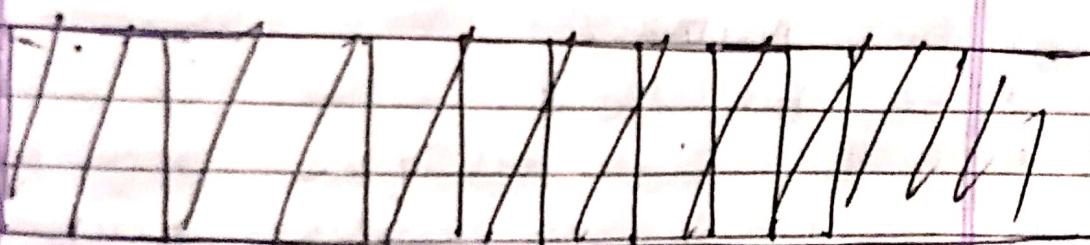

$$= 3.098 \times 10^6 \text{ Hz}$$

$$\boxed{B = 3.1 \text{ MHz}}$$

2x1)

- ~~This~~ TCP is transport layer protocol.
- It continuously receives data from the application layer

## TCP Header

TCP Header									
Source port					Destination port				
sequence number					acknowledgement number				
window					advt. window				
urg. pointer					options				
(0-40 bytes)					padding (optional)				

Source port

• 16 bit field

• port of the sending app.

destination port

• 16 bit field

• identifies the port of receiving application

③ Seq Number

• 32 bit field

• TCP assigns unique seq numbers  
contains the sequence number  
of first data byte

④ Acknowledgment Number

• 32 bit field

• It contains sequence number of  
data byte

• It always sequence number of  
a last received data byte

5) Header length

• 4 bit field

• contain the length of TCP

• It helps in knowing from where the data begin.

6) Reserved bit

6 bit field

These bits are not used

7) URG bit

It indicates the receiver that certain amount of data within current seg.

8) Ack bit

for all seg except request

Ack bit set to 1

push the entire buffer

9) PSH → No wait is done

10) RST → TCP connection

Transfer of data done

11) SYN → Request segment sent

↓  
for connection  
for synchronization

RST → Determine to terminate  
the TCP connection

WINDOW SIZE

16 bit

how much data sender  
can receive without ACK.

### Flags

Indicate to particular state  
connection or to provide some  
additional useful information

2(a) Run dig kstd

	$d(r)$	$d(a)$	$d(b)$	$d(c)$	$d(d)$	$d(s)$

vi)	0	2	5	7	8	10

path are

$x \rightarrow a \rightarrow b \rightarrow d \rightarrow s$

Ques) for the following num  
vector algo

1.  $\vec{a} = 2\hat{i} + 3\hat{j}$   
2.  $\vec{b} = 3\hat{i} - 2\hat{j}$   
3.  $\vec{c} = 4\hat{i} + \hat{j}$   
4.  $\vec{d} = -\hat{i} + 2\hat{j}$

Find the value of  
 $a) \vec{a} + \vec{b} + \vec{c} + \vec{d}$   
 $b) \vec{a} - \vec{b} + \vec{c} - \vec{d}$   
 $c) \vec{a} + \vec{b} - \vec{c} + \vec{d}$   
 $d) \vec{a} - \vec{b} - \vec{c} - \vec{d}$

Ans)  $\vec{a} + \vec{b} + \vec{c} + \vec{d} = 8\hat{i} + 2\hat{j}$   
 $\vec{a} - \vec{b} + \vec{c} - \vec{d} = 6\hat{i} + 4\hat{j}$   
 $\vec{a} + \vec{b} - \vec{c} + \vec{d} = 2\hat{i} + 0\hat{j}$   
 $\vec{a} - \vec{b} - \vec{c} - \vec{d} = -2\hat{i} - 2\hat{j}$

(b)

(a) Data - 100100

0	0	0	P <sub>4</sub>	1	0	0	P <sub>3</sub>	1	P <sub>2</sub>	P <sub>1</sub>
11	10	9	8	7	6	5	4	3	2	1

parity bits  $2^0 = 1$

$$2^2 = 4$$

$$2^3 = 8$$

$$2^4 = 16$$

P<sub>1</sub> = bits  $\Rightarrow$  3, 5, 7, 9, 11

P<sub>2</sub> = bits  $\Rightarrow$  3, 6, 7, 10, 11

P<sub>3</sub> = bits  $\Rightarrow$  5, 6, 7

P<sub>4</sub> = bits  $\Rightarrow$  9, 10, 11

P<sub>1</sub> = 1 because

Total no of 1 at position 1  
is one which is odd

P<sub>2</sub> = 0 because

No of 1 on 3, 6, 7, 10, 11 is two  
which is even

B Pg 21

### Hamming code

0	0	0	0	1	0	0	1	1	0	1
11	10	9	8	7	6	5	4	3	2	1

- b) Here it is given that the sixth bit is having error i.e. it is changed from 0 to 1 so receiver gets

0	0	0	0	1	1	0	1	1	0	1
11	10	9	8	7	6	5	4	3	2	1

Since there is error therefore new parity value

0	0	0	0	1	1	1	0	1	1	0
1	0	0	0	0	1	1	0	1	1	0

0 0 0 0 1 1 0 1 1 0 1

0 0 0 0 1 1 1 0 1 1 0 1

Since we note that there  
change in parity bits therefore

To correct the order

The new parity bit sequence  
is 0110 which is 6 in  
decimal

0 0 0 0 1 1 0 1 1 0 1 0  
11 10 9 8 7 6 5 4 3 2 1

If the link between B and C  
is disconnected then B will  
be aware that it can  
no longer reach C through

that links and will remove it from its table. But before doing it is possible that it will receive an update from A which we

say that it can reach C at a cost of 2 and B can get to A at a cost say 1 so it will update a route to C via A at a cost of 3.

A will then receive update from B and update it cost to 4. This way both the routers will keep on sending bad info to each other till infinity which is called as count to infinity problem

~~Q1~~ 3<sup>rd</sup> octet of netmask 2:

11111100

3<sup>rd</sup> octet of machine 6

10101000 & op result: 10101000

3<sup>rd</sup> octet of machine 7

10101001 & op result 10101000

3<sup>rd</sup> octet of m

~~Q2~~ ans

To get the subnet id. we need to perform AND operation on the IP add.

255 has all 1's whereas 0 has all 0's therefore performing AND operation on the third octet is enough

as first two octet will always be 172.68 for first 5 machine and 172.80 for last 5 machine

machine 1:

	3rd octet	of result
machine 1	10100000	10100000
" 2	10110011	10110000
" 3	10110001	10110000
" 4	10110010	10110000
" 5	10100010	10100000

3rd octet of netmask 2 : 11111100

machine 6	10101000	10101000
" 7	10101001	10101000
" 8	10101100	10101100
" 9	10101100	10101100
" 10	10101101	10101100
